

MIRI Target Acquisitions

The JWST [Mid-Infrared Instrument \(MIRI\)](#) provides target acquisition (TA) capabilities for the [low-resolution spectroscopy](#), [medium-resolution spectroscopy](#), and [coronagraphic imaging](#) modes.

Overview of MIRI target acquisitions

Parent page: [MIRI Operations](#)

Target acquisition (TA) is a procedure that centroids a source and places it accurately within an aperture, region of interest (ROI), or [subarray](#). The filters available for MIRI TA are F560W, F1000W, F1500W, and FND. TA procedures are discussed in the context of the observatory in memos and reports by [Gordon & Meixner \(2008\)](#), [Meixner et al. \(2006\)](#), [Nelán et al. \(2005\)](#), and [Meixner et al. \(2004\)](#).

TA procedures within the [Astronomer's Proposal Tool \(APT\)](#) are available for:

- [Low-resolution spectroscopy](#)
- [Medium-resolution spectroscopy](#)
- [Coronagraphic imaging](#)
- [Imaging](#)
